# Dark matter constraints in the minimal and nonminimal SUSY standard model

A. Stephan

Universität Dortmund, Institut für Physik,  
D-44221 Dortmund, Germany

## Abstract

We determine the allowed parameter space and the particle spectra of the minimal SUSY standard model (MSSM) and nonminimal SUSY standard model (NMSSM) imposing correct electroweak gauge-symmetry breaking and recent experimental constraints. The parameters of the models are evolved with the SUSY RGEs assuming universality at the GUT scale. Applying the new unbounded from below (UFB) constraints we can exclude the LSP singlinos and light scalar and pseudoscalar Higgs singlets of the NMSSM. This exclusion removes the experimental possibility to distinguish between the MSSM and NMSSM via the recently proposed search for an additional cascade produced in the decay of the bino into the LSP singlino. Furthermore the effects of the dark matter condition for the MSSM and NMSSM are investigated and the differences concerning the parameter space, the SUSY particle and Higgs sector are discussed.

# 1 Introduction

If the standard model (SM) is embedded in a grand unified theory (GUT), finetuning is needed in order to have a Higgs mass of the order of the electroweak scale and not the GUT scale. The quadratic divergences in the radiative corrections to the Higgs mass are the reason for this naturalness problem in the SM. SUSY models have the advantage of being free of quadratic divergences due to cancellations in Feynman graphs with particles and their supersymmetric partners. The simplest SUSY extension of the SM is the minimal SUSY standard model (MSSM) [1, 2] with two Higgs doublets  $H_1$  and  $H_2$ . However the MSSM has also a naturalness problem why the  $\mu$ -parameter of the term  $\mu H_1 H_2$  in the superpotential should be much smaller than the Planck mass. The nonminimal SUSY standard model (NMSSM) [3] is a minimal extension of the MSSM. In this model a Higgs singlet  $N$  is added to the Higgs sector of the MSSM. Moreover the  $\mu$ -parameter of the MSSM can be dynamically generated via  $\mu = \lambda x$  with the term  $\lambda H_1 H_2 N$  in the superpotential of the NMSSM, if the Higgs singlet acquires a vacuum expectation value (VEV)  $\langle N \rangle = x$ . SUSY models with Higgs singlets can be derived from superstring inspired  $E_6$  or  $SU(5) \times U(1)$  GUT models and they offer the possibility of spontaneous breaking of the CP symmetry. The discrete  $\mathbb{Z}_3$  symmetry of the NMSSM causes a domain wall problem. In the early universe the  $\mathbb{Z}_3$  symmetry is spontaneously broken during the electroweak phase transition. Domains of different degenerate vacua develop which are separated by domain walls. Since these domain walls would dominate the energy density of the universe and disturb primordial nucleosynthesis, they have to disappear before the onset of nucleosynthesis. Possible solutions to the domain wall problem and the hierarchy problem reintroduce the terms  $\mu H_1 H_2$  and  $\mu' N^2$  in the superpotential of the NMSSM and possess a gauged R-symmetry or a target space duality symmetry at the Planck scale [4]. In these more general models the NMSSM is approximated for very small values of the parameters  $\mu$  and  $\mu'$ .

The addition of a Higgs singlet superfield leads to two extra Higgses and one extra neutralino in the NMSSM compared to the particle spectrum of the MSSM. Since the Higgs singlets and the singlino  $\tilde{N}$  can mix with the other Higgses and neutralinos, the phe-

nomenology of the NMSSM may be modified compared to the MSSM. The phenomenology of the NMSSM has been investigated in several papers [5] - [15]. In SUSY models with R-parity conservation the lightest SUSY particle (LSP) cannot decay and is therefore stable. Especially a neutral LSP like the lightest neutralino is a good candidate for cold dark matter. In the MSSM the dark matter neutralino is mostly a bino. In the NMSSM there exists the alternative of a dark matter neutralino with a larger singlino portion. The cosmology of these dark matter singlinos has been discussed in [16] at a given fixed low energy scale. The experimentally and cosmologically allowed parameter space of the NMSSM and the dark matter neutralinos have been investigated in [17] using SUSY RG evolutions.

In the present paper we compare the allowed parameter space and the particle spectra of the MSSM and NMSSM. Assuming universality at the GUT scale the parameters of the models are evolved to the electroweak scale with the SUSY RGEs (given in [18] and Appendix A2 for the NMSSM). The Higgs potential is minimized and additional theoretical constraints and recent experimental bounds are imposed. Besides charge and color breaking (CCB) constraints we include here new unbounded from below (UFB) constraints [19]. Furthermore the consequences of the dark matter condition for the MSSM and NMSSM are investigated. In the present paper we give a more detailed analysis of the two models and the dark matter condition than in our previous paper [20].

In section 2 we introduce the NMSSM. The additional theoretical and experimental constraints are discussed in section 3. In section 4 we describe the dark matter constraints. The procedure of finding solutions of the NMSSM is explained in section 5. In section 6 the parameter space and the particle spectra of the MSSM and NMSSM are investigated without and with the dark matter condition. In Appendix A1 we give the complete formulas for the neutralino annihilation cross section in the NMSSM which are needed to calculate the relic neutralino density. In Appendix A2 the SUSY RGEs [18] for the NMSSM are listed.

## 2 The NMSSM

The Higgs sector of the MSSM consists of two Higgs doublets  $H_1$  and  $H_2$ . In the NMSSM [3] an additional Higgs singlet  $N$  is introduced. The superpotential of the NMSSM contains only Yukawa terms with dimensionless couplings

$$W = h_d H_1^T \epsilon \tilde{Q} \tilde{D} - h_u H_2^T \epsilon \tilde{Q} \tilde{U} + \lambda H_1^T \epsilon H_2 N - \frac{1}{3} k N^3. \quad (1)$$

$\tilde{Q}$  is a squark doublet.  $\tilde{U}$  and  $\tilde{D}$  are up-type and down-type squark singlets.  $\epsilon$  is the antisymmetric tensor with  $\epsilon_{12} = 1$ . The SUSY breaking is parametrized by different types of SUSY soft breaking terms in the lagrangian:

$$\begin{aligned} \mathcal{L}_{soft} = & -m_{H_1}^2 |H_1|^2 - m_{H_2}^2 |H_2|^2 - m_N^2 |N|^2 - m_Q^2 |\tilde{Q}|^2 - m_U^2 |\tilde{U}|^2 - m_D^2 |\tilde{D}|^2 \\ & - h_d A_d H_1^T \epsilon \tilde{Q} \tilde{D} + h_u A_u H_2^T \epsilon \tilde{Q} \tilde{U} \\ & + \lambda A_\lambda H_1^T \epsilon H_2 N + \frac{1}{3} k A_k N^3 \\ & + \frac{1}{2} M_3 \lambda_3 \lambda_3 + \frac{1}{2} M_2 \lambda_2^a \lambda_2^a + \frac{1}{2} M_1 \lambda_1 \lambda_1 + h.c. \end{aligned} \quad (2)$$

In SUSY models the tree-level scalar potential is given by the formula:

$$V_{tree} = \frac{1}{2} \sum (D^a)^2 + \sum F_i^* F_i + V_{soft} \quad (3)$$

$$D^a = g_a A_i^* T_{ij}^a A_j, \quad (4)$$

$$F_i = - \left( \frac{\partial W}{\partial A_i} \right)^* \quad (5)$$

where  $A_i$  are scalar fields and  $T_{ij}^a$  are the gauge group generators. The part of the scalar potential with only Higgs fields corresponds to the Higgs potential. The neutral part of the tree-level Higgs potential is given by:

$$\begin{aligned} V_{tree}^{Higgs} = & m_{H_1}^2 |H_1^0|^2 + m_{H_2}^2 |H_2^0|^2 + m_N^2 |N|^2 + \lambda^2 (|H_1^0|^2 + |H_2^0|^2) |N|^2 + \lambda^2 |H_1^0|^2 |H_2^0|^2 \\ & + k^2 |N|^4 - \lambda k H_1^0 H_2^0 N^{*2} - \lambda A_\lambda H_1^0 H_2^0 N - \frac{1}{3} k A_k N^3 \\ & + \frac{1}{8} (g_y^2 + g_2^2) (|H_1^0|^2 - |H_2^0|^2)^2 + h.c. \end{aligned} \quad (6)$$

In order to calculate the Higgs VEVs reliably we use the effective 1 loop Higgs potential consisting of the tree-level Higgs potential and the radiative corrections

$$V_{1loop}^{Higgs} = V_{tree}^{Higgs} + V_{rad}^{Higgs}. \quad (7)$$

The radiative corrections [6] to the effective Higgs potential arising from all particles and antiparticles with field-dependent mass  $m_i$ , spin  $S_i$  and color degrees of freedom  $C_i$  are given by

$$V_{rad}^{Higgs} = \frac{1}{64 \pi^2} \sum_i C_i (-1)^{2S_i} (2S_i + 1) m_i^4 \ln\left(\frac{m_i^2}{Q^2}\right). \quad (8)$$

$Q$  is the renormalisation scale which we take to be equal to the electroweak scale  $M_{weak} \simeq 100 \text{ GeV}$ . Here we only consider the important contributions of the top quark and stops  $\tilde{t}_{1,2}$ . The electroweak gauge-symmetry  $SU(2)_I \times U(1)_Y$  is spontaneously broken to the electromagnetic gauge-symmetry  $U(1)_{em}$  by the Higgs VEVs  $\langle H_i^0 \rangle = v_i$  with  $i = 1, 2$  and  $\langle N \rangle = x$ . The local minimum of the effective 1 loop Higgs potential is determined by the three minimum conditions for the VEVs:

$$\frac{1}{2} m_Z^2 = \frac{m_{H_1}^2 + \Sigma^1 - (m_{H_2}^2 + \Sigma^2) \tan^2 \beta}{\tan^2 \beta - 1} - \lambda^2 x^2 \quad (9)$$

$$\sin(2\beta) = \frac{2 \lambda x (A_\lambda + k x)}{m_{H_1}^2 + \Sigma^1 + m_{H_2}^2 + \Sigma^2 + 2 \lambda^2 x^2 + \lambda^2 v^2} \quad (10)$$

$$(m_N^2 + \Sigma^3) x^2 - k A_k x^3 + 2 k^2 x^4 + \lambda^2 x^2 v^2 - \frac{1}{2} (A_\lambda + 2 k x) \lambda x v^2 \sin(2\beta) = 0 \quad (11)$$

where  $v = \sqrt{v_1^2 + v_2^2} = 174 \text{ GeV}$ ,  $\tan \beta = v_2/v_1$  and  $\Sigma^i = \partial V_{rad}^{Higgs} / \partial v_i^2$ .

The neutralinos are Majorana particles and mixed states of the gauginos and Higgsinos. The mass and composition of the neutralinos is defined by the following part of the lagrangian

$$\mathcal{L} = -\frac{1}{2} \Psi^T M \Psi + h.c. \quad (12)$$

$$\Psi^T = (-i\lambda_1, -i\lambda_2^3, \Psi_{H_1}^0, \Psi_{H_2}^0, \Psi_N). \quad (13)$$

In this basis the symmetric mass matrix  $M$  of the neutralinos has the form:

$$\begin{pmatrix} M_1 & 0 & -m_Z \sin \theta_W \cos \beta & m_Z \sin \theta_W \sin \beta & 0 \\ 0 & M_2 & m_Z \cos \theta_W \cos \beta & -m_Z \cos \theta_W \sin \beta & 0 \\ -m_Z \sin \theta_W \cos \beta & m_Z \cos \theta_W \cos \beta & 0 & \lambda x & \lambda v_2 \\ m_Z \sin \theta_W \sin \beta & -m_Z \cos \theta_W \sin \beta & \lambda x & 0 & \lambda v_1 \\ 0 & 0 & \lambda v_2 & \lambda v_1 & -2 k x \end{pmatrix}.$$

With  $\mu = \lambda x$  the first  $4 \times 4$  submatrix recovers the mass matrix of the MSSM [2]. The mass of the neutralinos is here obtained by diagonalising the mass matrix  $M$  with the orthogonal matrix  $N$ . (Then some mass eigenvalues may be negative [21].)

$$\mathcal{L} = -\frac{1}{2} m_i \bar{\tilde{\chi}}_i^0 \tilde{\chi}_i^0 \quad (14)$$

$$\tilde{\chi}_i^0 = \begin{pmatrix} \chi_i^0 \\ \bar{\chi}_i^0 \end{pmatrix} \text{ with } \chi_i^0 = N_{ij} \Psi_j \text{ and } M_{diag} = N M N^T. \quad (15)$$

The neutralinos  $\tilde{\chi}_i^0$  ( $i = 1 - 5$ ) are ordered with increasing mass  $|m_i|$ , thus  $\tilde{\chi}_1^0$  is the LSP neutralino. The matrix elements  $N_{ij}$  ( $i, j = 1 - 5$ ) describe the composition of the neutralino  $\tilde{\chi}_i^0$  in the basis  $\Psi_j$  (Eq.(13)). For example the bino portion of the LSP neutralino is given by  $N_{11}^2$  and the singlino portion of the LSP neutralino by  $N_{15}^2$ . The diagonalising of the mass matrix  $M$  leads to a polynomial equation of degree 5, which cannot be solved analytically in general. Therefore we calculate the eigenvalues and eigenvectors of the symmetric mass matrix  $M$  numerically by using a subroutine in the NAG Fortran Library.

The possibility of gauge coupling unification is an important motivation for SUSY GUTs. In contrast to non-supersymmetric GUTs [22], the gauge couplings in SUSY GUTs are allowed to unify  $g_a(M_X) = g_5 \simeq 0.72$  at a scale  $M_X \simeq 1.6 \times 10^{16} \text{ GeV}$ . Within a minimal  $N = 1$  supergravity framework universality naturally arises for the SUSY soft breaking parameters:

$$\begin{aligned} m_i(M_X) &= m_0 \\ M_a(M_X) &= m_{1/2} \\ A_i(M_X) &= A_0 \quad (A_\lambda(M_X) = -A_0). \end{aligned} \quad (16)$$

The Yukawa couplings at the GUT scale take the values  $\lambda(M_X) = \lambda_0$ ,  $k(M_X) = k_0$  and  $h_t(M_X) = h_{t0}$ . With the SUSY RGEs ([18], Appendix A2) the SUSY soft breaking parameters and the Yukawa couplings are evolved from the GUT scale to the electroweak scale  $M_{weak}$ . At  $M_{weak}$  we minimize the effective 1 loop Higgs potential  $V_{1loop}^{Higgs}$  (Eq.(7)).

### 3 Theoretical and experimental constraints

The solutions of the SUSY RGEs ([18], Appendix A2) have to fulfill several theoretical and experimental constraints. The minimum of the effective 1 loop Higgs potential  $V_{1loop}^{Higgs}$

(Eq.(7)) should be not only a local minimum but also a stable minimum. A local minimum is stable against tunnelling into a lower minimum, if its lifetime is large enough (of the order of the age of the universe). A global minimum is certainly stable, but it may be difficult to prove, that it is really a global minimum. Here we only investigate, whether the physical minimum is lower than the unphysical minima of  $V_{loop}^{Higgs}(v_1, v_2, x)$  with at least one vanishing VEV [5].

The conservation of charge and color would be broken by slepton and squark VEVs. To avoid a scalar potential with such a minimum, the trilinear couplings have to fulfill the following conditions [18]:

$$A_{u_i}^2 \leq 3(m_{H_2}^2 + m_{Q_i}^2 + m_{U_i}^2) \text{ at scale } Q \sim A_{u_i}/h_{u_i} \quad (17)$$

$$A_{d_i}^2 \leq 3(m_{H_1}^2 + m_{Q_i}^2 + m_{D_i}^2) \text{ at scale } Q \sim A_{d_i}/h_{d_i} \quad (18)$$

$$A_{e_i}^2 \leq 3(m_{H_1}^2 + m_{L_i}^2 + m_{E_i}^2) \text{ at scale } Q \sim A_{e_i}/h_{e_i}. \quad (19)$$

In [19] improved charge and color breaking (CCB) constraints and unbounded from below (UFB) constraints are analysed for the MSSM. The by far strongest of these new constraints is the UFB-3 constraint (Eq.(33) in the first publication of Ref.[19]), in contrast to the remaining ones. To apply the UFB-3 constraint to the NMSSM we have to modify the formulas in [19]: In the NMSSM a dangerous field direction of the tree-level scalar potential  $V_{tree}$  (Eq.(3)) occurs for VEVs of the neutral Higgs  $H_2^0$ , the electron sneutrino  $\tilde{\nu}_e$  denoted by  $L_1 = \tilde{L}_1^0$  and the staus  $\tilde{\tau}_L^-$  and  $\tilde{\tau}_R^+$  denoted by  $\tilde{L}_3^-$  and  $\tilde{E}_3$ . The VEVs of the staus are introduced in order to cancel the F-term of  $H_1^0$ :

$$\left| \frac{\partial W}{\partial H_1^0} \right|^2 = |\lambda x H_2^0 + h_\tau \tilde{L}_3^- \tilde{E}_3|^2 = 0. \quad (20)$$

For the VEVs of the staus we choose the relation  $e = \tilde{L}_3^- = \tilde{E}_3$ . In analogy to the MSSM we have replaced in Eq.(20)  $\mu$  by  $\lambda x$  where the Higgs singlet VEV  $\langle N \rangle = x$  is determined by the physical minimum of the NMSSM Higgs potential. Since we consider here the scalar potential and not only the Higgs potential, the Higgs singlet VEV  $x$  may be optimized further. But here we don't investigate this more general case. The NMSSM tree-level scalar potential along the described field direction is given by:

$$V_{tree} = m_{H_2}^2 |H_2^0|^2 + (m_{L_3}^2 + m_{E_3}^2) |e|^2 + m_{L_1}^2 |L_1|^2$$

$$\begin{aligned}
& + \frac{1}{8} (g_y^2 + g_2^2) (|H_2^0|^2 + |e|^2 - |L_1|^2)^2 \\
& + m_N^2 x^2 - \frac{2}{3} k A_k x^3 + k^2 x^4.
\end{aligned} \tag{21}$$

Now we can determine the dangerous field direction of  $V_{tree}$  (Eq.(21)), which is given by:

$$|L_1|^2 = \frac{-4 m_{L_1}^2}{g_y^2 + g_2^2} + |H_2^0|^2 + |e|^2, \tag{22}$$

$$|e| = \sqrt{\frac{|\lambda x|}{h_\tau} |H_2^0|} \tag{23}$$

provided that

$$|H_2^0| > \sqrt{\frac{(\lambda x)^2}{4 h_\tau^2} + \frac{4 m_{L_1}^2}{g_y^2 + g_2^2}} - \frac{\lambda x}{2 h_\tau}. \tag{24}$$

For smaller values of  $|H_2^0|$  we obtain  $|L_1| = 0$ . In the field direction of Eq.(22) and (23) the tree-level scalar potential of the NMSSM reads:

$$\begin{aligned}
V_{UFB-3} &= (m_{H_2}^2 + m_{L_1}^2) |H_2^0|^2 + \frac{|\lambda x|}{h_\tau} (m_{L_3}^2 + m_{E_3}^2 + m_{L_1}^2) |H_2^0| \\
&- \frac{2 m_{L_1}^4}{g_y^2 + g_2^2} + m_N^2 x^2 - \frac{2}{3} k A_k x^3 + k^2 x^4.
\end{aligned} \tag{25}$$

For  $|L_1| = 0$  the tree-level scalar potential is given by:

$$\begin{aligned}
V_{UFB-3} &= m_{H_2}^2 |H_2^0|^2 + \frac{|\lambda x|}{h_\tau} (m_{L_3}^2 + m_{E_3}^2) |H_2^0| \\
&+ \frac{1}{8} (g_y^2 + g_2^2) \left( |H_2^0|^2 + \frac{|\lambda x|}{h_\tau} |H_2^0| \right)^2 + m_N^2 x^2 - \frac{2}{3} k A_k x^3 + k^2 x^4.
\end{aligned} \tag{26}$$

Since the tree-level scalar potential  $V_{UFB-3}$  should be larger than the physical minimum of the tree-level Higgs potential  $V_{tree}^{Higgs}$  (Eq.(6)), the UFB-3 constraint can be written as

$$V_{UFB-3}(Q = \hat{Q}) > (V_{tree}^{Higgs}(Q = M_S))_{Min}. \tag{27}$$

The tree-level Higgs potential  $V_{tree}^{Higgs}$  (Eq.(6)) is minimized at the scale  $Q = M_S$ , where the radiative corrections  $V_{rad}^{Higgs}$  (Eq.(8)) are very small.  $M_S$  turns out to be a certain average of SUSY masses. For the same reason the tree-level scalar potential  $V_{UFB-3}$  is evaluated at the scale  $Q = \hat{Q} \sim \text{Max}(g_2 |e|, g_2 |H_2^0|, h_t |H_2^0|, g_2 |L_1|, M_S)$ . Since  $V_{UFB-3}(Q = \hat{Q})$  depends on  $|H_2^0|$  the relation (27) should be fulfilled for all  $|H_2^0|$  values below  $M_X$ .

Because we assume  $h_t \gg h_b, h_\tau$ , we restrict  $|\tan\beta|$  to be smaller than 20 [7]. For the Higgs singlet VEV  $x$  we choose the range  $|x| < 80 \text{ TeV}$  [7, 8, 13]. In the present paper we choose the parameters  $m_0$  and  $|m_{1/2}|$  to be smaller than  $1500 \text{ GeV}$ . This restriction is motivated by requiring the absence of too much fine-tuning [13], which disfavors solutions with enormous sensitivity of  $m_Z$  to the GUT scale parameters  $h_{t0}$  or  $\lambda_0$  and  $k_0$ . The dark matter constraints further restrict the allowed parameter region of  $m_0$  and  $|m_{1/2}|$  as shown in Fig.1.

For the top quark pole mass we take the range  $169 \text{ GeV} < m_t < 181 \text{ GeV}$  corresponding to the recent world average measurement [23]. Since charged or colored massive stable particles are cosmologically disfavored LSPs, we assume the lightest neutralino to be the LSP and impose the constraints  $m_{\tilde{\chi}_1^0} < m_{\tilde{\tau}_1}$  and  $m_{\tilde{\chi}_1^0} < m_{\tilde{t}_1}$ . The SUSY particles in the NMSSM have to fulfill the following experimental conditions:  $m_{\tilde{\nu}} \geq 41.8 \text{ GeV}$  [24],  $m_{\tilde{e}_R} \geq 70 \text{ GeV}$  [25],  $m_{\tilde{q}} \geq 176 \text{ GeV}$  (if  $m_{\tilde{g}} < 300 \text{ GeV}$ ) [24] and  $m_{\tilde{q}} \geq 70 \text{ GeV}$  (for all  $m_{\tilde{g}}$ ) [26],  $m_{\tilde{t}_1} \geq 63 \text{ GeV}$  [25],  $m_{\tilde{g}} \geq 173 \text{ GeV}$  [27],  $m_{\tilde{\chi}_1^+} \geq 85.4 \text{ GeV}$  [28],  $m_{H^+} \geq 52 \text{ GeV}$  [29],  $m_{S_1} \geq 74 \text{ GeV}$  [30] or the coupling of the lightest scalar Higgs  $S_1$  to the Z boson is reduced compared to the SM [31] assuming visible decays with branching ratios like the SM Higgs [8], and

$$\sum_{i,j} \Gamma(Z \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0) < 30 \text{ MeV} \quad [32]$$

$$\Gamma(Z \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0) < 7 \text{ MeV} \quad [32]$$

$$BR(Z \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0) < 10^{-5}, \quad (i,j) \neq (1,1) \quad [32].$$

## 4 Dark matter constraints

Inflationary cosmological models are proposed to solve the flatness, horizon and magnetic monopole problem. In these models the universe is flat with a density equal to the critical density  $\rho_{crit} = 1.054 \times 10^{-5} h_0^2 \text{ GeV}/\text{cm}^3$  implying a cosmological density parameter of  $\Omega = \rho/\rho_{crit} = 1$ . The Hubble constant  $H_0 = 100 h_0 \text{ km s}^{-1} \text{ Mpc}^{-1}$  is restricted by observations to the range  $0.4 < h_0 < 1$  of the scaled Hubble constant  $h_0$ . To be consistent with the observed abundances of the isotopes  $D$ ,  $^3\text{He}$ ,  $^4\text{He}$  and  $^7\text{Li}$  the big bang

nucleosynthesis model restricts the baryon density to  $\Omega_{baryons} \leq 0.1$ . The discrepancy between the cosmological density  $\Omega = \rho/\rho_{crit} = 1$  and the baryon density requires a huge amount of dark matter in the universe. One of the favored theories to explain the structure formation of the universe is the cold + hot dark matter model (CHDM) [33]. In this model the dark matter consists of hot dark matter (massiv neutrinos) and cold dark matter (neutralinos) with  $\Omega_{hot} \simeq 0.3$  and  $\Omega_{cold} \simeq 0.65$ . With the allowed range of the scaled Hubble constant  $h_0$  the condition for the relic density of the neutralinos in the CHDM model reads

$$0.1 \leq \Omega_\chi h_0^2 \leq 0.65. \quad (28)$$

The relic neutralino density can be calculated by solving the Boltzmann equation for the early universe. The Boltzmann equation describes the particle densities in the cosmic plasma governed by the annihilation cross section. The annihilation cross section of the neutralinos can be expanded in powers of the relative velocity  $v$  of the non-relativistic neutralinos:  $\sigma_{ann}v = a + bv^2$ . The thermally averaged annihilation cross section [34] - [36] is then given by  $\langle \sigma_{ann}v \rangle = x^{1.5} / (2\sqrt{\pi}) \int_0^\infty dv v^2 \exp\{-x v^2 / 4\} \sigma_{ann}v = a + 6b/x$  with  $x = |m_{\tilde{\chi}_1^0}| / T$ . During the expansion of the universe its temperature falls and reaches the freeze-out temperature of the neutralinos  $T_{fr}$ , at which the neutralinos drop out of the thermal equilibrium with the cosmic plasma. The freeze-out temperature of the neutralinos  $T_{fr}$  follows from the equation [34] - [37]

$$x_{fr} = \ln \left( 0.0764 |m_{\tilde{\chi}_1^0}| M_P \frac{\langle \sigma_{ann}v \rangle}{\sqrt{g_*} x_{fr}} c (2 + c) \right), \quad (29)$$

where  $M_P = 1.221 \times 10^{19} GeV$  is the Planck mass,  $g_* \approx 81$  is the effective number of degrees of freedom at  $T_{fr}$  and  $c = 1/2$ . With  $J(x_{fr}) = \int_{x_{fr}}^\infty dx / x^2 \langle \sigma_{ann}v \rangle = a/x_{fr} + 3b/x_{fr}^2$  [34] - [36] the relic neutralino density [34] - [37] is given by

$$\Omega_\chi h_0^2 = \frac{1.07 \times 10^9}{\sqrt{g_*} M_P J(x_{fr}) GeV}. \quad (30)$$

The expansion of the annihilation cross section  $\sigma_{ann}v = a + bv^2$  is not a good approximation in the vicinity of poles or thresholds [38]. In the present work the case of coannihilation is not important [17, 39], since the LSP neutralino in the MSSM and NMSSM is mostly bino-like or a mixed state with small mass (see Fig.4). Furthermore the LSP singlinos

[9, 10, 13] of the NMSSM are now excluded by the UFB-3 constraint (Eq.(27)) as discussed in section 6.

Compared to the MSSM the annihilation cross section of the neutralinos changes in the NMSSM because of more particles in this model, which can mix, and modified vertices. In our numerical analysis we consider all possible decay channels. The relevant formulas for the NMSSM are given in the Appendix A1. They are obtained by substituting the MSSM couplings in [34] by the corresponding NMSSM couplings and by slightly modifying the partial wave amplitudes in [34].

## 5 Procedure of finding solutions

The SUSY soft breaking parameters  $m_i$  and  $A_i$  and the Yukawa couplings  $\lambda$ ,  $k$  and  $h_t$  are evolved with the SUSY RGEs ([18], Appendix A2) from the GUT scale  $M_X$  to the electroweak scale  $M_{weak}$ . Since we assume universality at the GUT scale  $M_X$  (Eq.(16)) we have only 6 GUT scale parameters  $m_0$ ,  $m_{1/2}$ ,  $A_0$ ,  $\lambda_0$ ,  $k_0$  and  $h_{t0}$ . Together with the low energy parameters  $\tan \beta$  and  $x$  there are 8 parameters in the NMSSM with only 5 of them being independent. In our procedure we take  $\lambda_0$ ,  $k_0$ ,  $h_{t0}$ ,  $\tan \beta$  and  $x$  as independent input parameters. The remaining 3 parameters ( $m_0$ ,  $m_{1/2}$ ,  $A_0$ ) are then determined by the three minimum conditions (9-11) and are numerically calculated by the method described in [7, 20]: The three minimum conditions (9-11) depend only on the low energy parameters  $m_i$ ,  $A_i$ ,  $\lambda$ ,  $k$  and  $h_t$  generically denoted by  $p_k(M_{weak})$ :

$$\frac{\partial V_{1loop}}{\partial v_i} = F_i(p_k) = 0 \quad (i = 1 - 3). \quad (31)$$

Since  $\lambda_0$ ,  $k_0$  and  $h_{t0}$  are (randomly choosen) fixed input parameters, all low energy parameters  $p_k(M_{weak})$  are functions  $f_k$  (which can be constant) of the GUT scale parameters  $m_0$ ,  $m_{1/2}$  and  $A_0$  only:

$$p_k(M_{weak}) = f_k(m_0, m_{1/2}, A_0). \quad (32)$$

To obtain the functions  $f_k$  we numerically solve the SUSY RGEs ([18], Appendix A2)  $dp_k/dt = h_k(t, p_1, \dots, p_n)$  ( $k = 1 - n$ ). A solution to a system of first-order differential

equations can be found with the method of Runge, Kutta and Merson. A subroutine for this numerical method is available in the CERN Program Library. An additional subroutine has to be written which calculates the derivatives  $dp_k/dt$  ( $k = 1 - n$ ) depending on the current values of  $t$  and  $p_1, \dots, p_n$ . In the three minimum conditions (31) we then substitute the low energy parameters  $p_k(M_{weak})$  by the functions  $f_k$  and obtain the generic equations

$$F_i(f_k(m_0, m_{1/2}, A_0)) = G_i(m_0, m_{1/2}, A_0) = 0 \quad (i = 1 - 3). \quad (33)$$

The SUSY breaking parameters  $m_0$ ,  $m_{1/2}$  and  $A_0$  are then determined by the zero points of the generic equations  $G_i(m_0, m_{1/2}, A_0) = 0$  ( $i = 1 - 3$ ). In order to find a solution of Eq.(33) we first minimize  $\sum_{i=1}^3 G_i(m_0, m_{1/2}, A_0)^2$  and then we check, whether the minimum is also a zero point. The minimization is performed by using the simplex method of Nelder and Mead. A corresponding minimization routine SIMPLEX is available in the MINUIT package of the CERN Program Library. The numerical procedure needs starting values for the parameters  $m_0$ ,  $m_{1/2}$  and  $A_0$ , which are randomly generated using a logarithmic measure within their ranges.

To obtain a representative sample of solutions of the NMSSM, we randomly generate  $\sim 4.3 \times 10^8$  points in the 5 dimensional parameter space of the input parameters  $\lambda_0$ ,  $k_0$ ,  $h_{t0}$ ,  $\tan \beta$  and  $x$  using a logarithmic measure. The SUSY breaking parameters  $m_0$ ,  $m_{1/2}$  and  $A_0$  are then numerically calculated with the three minimum equations (33). Having found a solution of the SUSY RGEs ([18], Appendix A2), whose effective 1 loop Higgs potential  $V_{1loop}^{Higgs}$  (Eq.(7)) has a local minimum for the input parameters  $\tan \beta$  and  $x$ , we impose the additional theoretical and experimental constraints described in section 3. The very strong UFB-3 constraint (Eq.(27)) excludes about 80% of the solutions which fulfill all the other constraints of section 3. For every solution we calculate the masses of all SUSY particles [2, 40] and Higgses [3, 6, 12, 13]. Altogether we obtain about 6600 solutions which fulfill all requirements. The ranges of the parameters, for which we find solutions, are given by  $m_0 \in [60 \text{ GeV}, 1500 \text{ GeV}]$ ,  $|m_{1/2}| \in [120 \text{ GeV}, 1500 \text{ GeV}]$ ,  $|A_0| \in [180 \text{ GeV}, 6000 \text{ GeV}]$ ,  $\lambda_0 \in [2 \times 10^{-3}, 0.5]$ ,  $k_0 \in [10^{-3}, 0.6]$ ,  $h_{t0} \in [0.4, 0.9]$ ,  $|\tan \beta| \in [2.4, 20]$  and  $|x| \in [800 \text{ GeV}, 80000 \text{ GeV}]$ . Applying the dark matter constraint to the 6600 solutions, about 1500 solutions remain which are cosmologically

acceptable.

## 6 Parameter space and particle spectra

In the following we investigate the parameter space and the particle spectra of the MSSM and NMSSM. The consequences of the dark matter condition for the two models are discussed. We show our results in the form of scatter-plots. Each point represents a solution of the SUSY RGEs (given in Appendix A2 for the NMSSM) with additional theoretical and experimental constraints imposed as described for the NMSSM in section 3. In the upper left picture of Fig.1 the MSSM solutions are shown in the  $(|m_{1/2}|, m_0)$  plane. The parameter region with small  $m_0$  and large  $|m_{1/2}|$  is excluded by the UFB-3 constraint [19]. Furthermore in the region  $|m_{1/2}| \gg m_0$  the stau or stop would be the LSP. But a charged or colored LSP like the stau or stop is cosmologically disfavored [41]. In the upper right picture the cosmologically allowed solutions are shown. The dark matter condition leads to an upper bound of  $600 \text{ GeV}$  for  $|m_{1/2}|$  and leaves  $m_0$  unconstrained. Values of  $m_0$  larger than about  $300 \text{ GeV}$  are cosmologically allowed due to Z-pole or Higgs-pole enhanced neutralino pair annihilation. Comparable scatter-plots for the constrained MSSM are discussed in [42]. In that paper upper bounds of  $940 \text{ GeV}$  for  $|m_{1/2}|$  and  $500 \text{ GeV}$  for  $m_0$  are deduced for  $m_t = 170 \text{ GeV}$ . The lower left picture shows the NMSSM solutions. The effect of the UFB-3 constraint (Eq.(27)) in the NMSSM is comparable to the MSSM. In the NMSSM this constraint also excludes the parameter region with small  $m_0$  and large  $|m_{1/2}|$ . The reason, why the case  $m_0 \gg |m_{1/2}|$  is suppressed in the NMSSM, is discussed in [9]. It follows from the condition, that the minimum of the scalar potential does not break the conservation of charge and color, and from the condition that the physical minimum is lower than the symmetric vacuum,  $9 m_0^2 \lesssim A_0^2$ . In the lower right picture the dark matter condition is imposed leading to an upper bound of  $650 \text{ GeV}$  for  $|m_{1/2}|$ . In contrast to the MSSM the upper bound for  $m_0$  is about  $300 \text{ GeV}$  in the NMSSM. These upper bounds follow from the cosmological upper bounds of  $260 \text{ GeV}$  for the LSP neutralino and  $450 \text{ GeV}$  for the lighter selectron as discussed in [20] and below. This can be understood from the fact [34], that the LSP neutralino in the NMSSM is mostly bino-like (see Fig.4)

and the annihilation cross section is dominated by sfermion exchange.

For the MSSM we show in the upper left picture of Fig.2 the solution points in the plane  $(m_0, |A_0|)$ . The upper bound for  $|A_0|$  follows from the UFB-3 constraint [19]. The upper right picture shows the cosmologically restricted solutions. The concentration of points corresponds to  $m_0$  values below about  $300\text{ GeV}$  in the upper right picture of Fig.1. Larger values of  $m_0$  are cosmologically allowed because of Z-pole or Higgs-pole enhanced neutralino pair annihilation. The lower left picture shows the allowed values of  $|A_0|$  in the NMSSM. Comparable with the MSSM the UFB-3 constraint (Eq.(27)) leads to an upper bound for  $|A_0|$  in the NMSSM. In contrast to the MSSM there is also a lower bound for  $|A_0|$  in the NMSSM. The NMSSM solutions have to fulfill the relation  $9 m_0^2 \lesssim A_0^2$  [9], which follows from the condition that the physical minimum has to be lower than the symmetric vacuum. The dark matter condition strongly restricts the allowed range of  $|A_0|$  as shown in the lower right picture. Larger values of  $m_0$  are cosmologically excluded, since  $m_0 \gg |m_{1/2}|$  is disfavored in the NMSSM as already discussed.

In the upper left picture of Fig.3 we show the MSSM solution points in the plane  $(\mu, |M_2|)$ . The parameters  $\mu$  and  $M_2$  are taken at the electroweak scale  $M_{weak}$ . The solutions are lying below the diagonals  $|M_2| = |\mu|$ . The reason is the first minimum condition which favors larger values of  $|\mu|$  for  $|\tan\beta| \rightarrow 1$ . The first minimum condition of the MSSM has the same form as the first minimum condition in the NMSSM (Eq.(9)) if  $\mu$  is substituted for  $\lambda x$ . This property of the solutions leads to bino-like LSP neutralinos in the MSSM (see Fig.4). In the upper right picture the dark matter condition is imposed. The upper bound of  $500\text{ GeV}$  for  $|M_2|$  corresponds to the upper bound of  $600\text{ GeV}$  for  $|m_{1/2}|$  in the upper right picture of Fig.1. The NMSSM solutions in the lower left picture are similar to the MSSM solutions, but they are more restricted. This restriction follows from the third minimum condition (Eq.(11)) in the NMSSM which would be an extra constraint for the MSSM. The lower right picture shows the cosmologically allowed solutions. The upper bound of  $550\text{ GeV}$  for  $|M_2|$  follows from the upper bound of  $650\text{ GeV}$  for  $|m_{1/2}|$  in the lower right picture of Fig.1.

In the upper left picture of Fig.4 the bino portion of the LSP neutralino  $|\tilde{B} \chi_1^0|^2$

versus the LSP neutralino mass is shown for the MSSM. The LSP neutralinos are mostly binos  $|\langle \tilde{B} | \tilde{\chi}_1^0 \rangle|^2 \approx 1$ , which follows from the first minimum condition in the MSSM corresponding to Eq.(9) as already discussed. The cosmologically allowed LSP neutralinos are shown in the upper right picture. The dark matter condition sets an upper bound of  $240 \text{ GeV}$  for the LSP neutralino mass corresponding to the upper bound of  $600 \text{ GeV}$  for  $|m_{1/2}|$  in the upper right picture of Fig.1. The lower bound for the mass of the LSP neutralinos is about  $40 \text{ GeV}$  in the MSSM. For the NMSSM the lower left picture shows the bino portion of the LSP neutralinos. Similarly to the MSSM most of the LSP neutralinos are binos in the NMSSM. If the UFB-3 constraint (Eq.(27)) is not applied, there exist a large fraction of decoupled pure LSP singlinos with  $|\langle \tilde{B} | \tilde{\chi}_1^0 \rangle|^2 = 0$  and a much smaller fraction of mixed LSP singlinos. In [10] the phenomenology of the LSP singlinos is investigated. The LSP singlinos are now excluded by the UFB-3 constraint (Eq.(27)), which excludes the parameter region with small  $m_0$  and large  $|m_{1/2}|$ . This is just the appropriate parameter region for LSP singlinos [9, 10, 13]. The lower right picture shows the cosmologically allowed LSP neutralinos in the NMSSM. The upper bound of  $260 \text{ GeV}$  for the LSP neutralino mass corresponds to the upper bound of  $650 \text{ GeV}$  for  $|m_{1/2}|$  in the lower right picture of Fig.1. The dark matter condition improves the lower bound for the LSP neutralinos in the NMSSM to  $50 \text{ GeV}$  as discussed in [20]. In the NMSSM all LSP neutralinos with mass  $m_{\tilde{\chi}_1^0} \approx m_Z/2$  are cosmologically excluded, since their coupling to the Z boson is larger due to a larger Higgsino portion.

In the upper left picture of Fig.5 the mass of the lighter chargino versus the mass of the lighter selectron is shown for the MSSM. The upper right picture shows the cosmologically allowed lighter chargino masses. The dark matter condition sets an upper bound of  $450 \text{ GeV}$  for the lighter chargino and disfavors somewhat selectron masses larger than about  $1 \text{ TeV}$ . Selectrons with  $300 \text{ GeV} \lesssim m_{\tilde{e}_R}$  are cosmologically allowed due to Z-pole or Higgs-pole enhanced neutralino pair annihilation [42]. For the NMSSM the lower left picture shows the mass of the lighter chargino versus the mass of the lighter selectron. Compared to the MSSM there are not so many solutions in the NMSSM with small chargino mass and large selectron mass following from the suppression of the domain  $m_0 \gg |m_{1/2}|$  in the NMSSM as discussed in [9]. In the lower right picture the dark matter

condition is imposed leading to an upper bound of  $500\text{ GeV}$  for the lighter chargino and a cosmologically allowed mass range of  $100\text{ GeV} < m_{\tilde{e}_R} < 450\text{ GeV}$  for the lighter selectron in the NMSSM. The cosmologically allowed solutions in the MSSM and NMSSM show some differences. Only in the MSSM there are cosmologically allowed heavier selectrons. In contrast to the MSSM, the dark matter condition leads to a slightly improved lower bound of  $90\text{ GeV}$  for the lighter chargino in the NMSSM. The reason is the enhanced lower bound of  $50\text{ GeV}$  for the cosmologically allowed LSP neutralinos in the NMSSM as discussed and shown in Fig.4 and the proportionality between the mass of the lighter chargino and the mass of the bino-like LSP neutralino.

In the upper left picture of Fig.6 the mass of the lighter u-squark versus the gluino mass is shown for the MSSM. The upper boundary line for the lighter u-squark mass results from the restriction of  $m_0$ . As mentioned in section 3 we have chosen  $m_0$  to be smaller than  $1500\text{ GeV}$  in order to avoid too much finetuning. The lower bound for the gluino and the lighter u-squark is  $250\text{ GeV}$ . In the upper right picture the cosmologically allowed lighter u-squark masses are shown. In many cases the cosmologically allowed lighter u-squark mass is proportional to the gluino mass. The deviations from proportionality with large u-squark masses follow from the Z-poles or Higgs-poles shown in the upper right picture of Fig.1. The dark matter condition leads to an upper bound of  $1600\text{ GeV}$  for the gluino following from the cosmological upper bound of  $240\text{ GeV}$  for the bino-like LSP neutralino. In the lower left picture the mass of the lighter u-squark is shown for the NMSSM. In contrast to the MSSM [43], the squark masses in the NMSSM are nearly proportional to the gluino mass as discussed in [20]. The reason is, that in the NMSSM solutions with  $m_0 \gg |m_{1/2}|$  are somewhat disfavored. In contrast to the MSSM the lower bound for the gluino is  $330\text{ GeV}$  in the NMSSM, which follows from the lower experimental bound of  $85.4\text{ GeV}$  [28] for the chargino and from the lower bound of about 2.4 for  $|\tan\beta|$  in the NMSSM (see Fig.8) as discussed in [9]. Excluding small values of  $m_0$  the UFB-3 constraint (Eq.(27)) further improves the lower bound for the lighter u-squark to  $370\text{ GeV}$ . In the lower right picture the dark matter condition is imposed. In contrast to the MSSM, the dark matter condition improves the lower bound for the gluino to  $370\text{ GeV}$  in the NMSSM as discussed in [20]. The reason is the enhanced lower bound of  $50\text{ GeV}$  and the larger

Higgsino portion of the lightest cosmologically allowed LSP neutralinos in the NMSSM. With the dark matter condition the lower bound for the lighter u-squark slightly improves to  $390 \text{ GeV}$ . The cosmological upper bound of  $1800 \text{ GeV}$  for the gluino in the NMSSM is similar to the corresponding upper bound in the MSSM. The upper bound of  $1600 \text{ GeV}$  for the lighter u-squark in the NMSSM corresponds to the upper bound for the lighter u-squark in the MSSM at large gluino masses.

In the upper left picture of Fig.7 the mass of the lighter stop versus the gluino mass is shown for the MSSM. The stop masses are restricted from above, since the  $m_0$  values have been chosen to be smaller than  $1500 \text{ GeV}$  as discussed in section 3. In the upper right picture the cosmologically allowed lighter stop masses are shown. Large stop masses at moderate gluino masses are allowed due to Z-poles and Higgs-poles. The dark matter condition sets an upper bound of  $1200 \text{ GeV}$  for the lighter stop at large gluino masses. In the lower left picture the lighter stop masses are shown for the NMSSM. In contrast to the MSSM [43], the lighter stop mass is nearly proportional to the gluino mass as discussed in [20] following from the suppression of the domain  $m_0 \gg |m_{1/2}|$  in the NMSSM. In addition the constraints for the trilinear couplings  $A_{u_i}$ ,  $A_{d_i}$  and  $A_{e_i}$  (Eqs.(17)-(19)) are stronger in the NMSSM than in the MSSM. The corresponding constraints in the MSSM are obtained by replacing  $m_{H_{1,2}}^2$  in (Eqs.(17)-(19)) by  $m_{H_{1,2}}^2 + \mu^2$ . The stronger constraints for the trilinear couplings lead to a larger mass of the stop in the NMSSM, since the stop mixing depends on  $A_t$ . Together with the UFB-3 constraint (Eq.(27)), which excludes small values of  $m_0$ , the lower bound for the lighter stop increases to  $240 \text{ GeV}$  in the NMSSM. The lower right picture shows the cosmologically restricted solutions. The lower bound for the lighter stop slightly improves to  $270 \text{ GeV}$ . The cosmological upper bound of  $1300 \text{ GeV}$  for the lighter stop in the NMSSM is similar to the corresponding upper bound for the lighter stop in the MSSM at large gluino masses.

In the upper left picture of Fig.8 we show the mass of the lighter scalar Higgs  $S_1$  versus  $|\tan\beta|$  for the MSSM. In the MSSM the mass of the scalar Higgs  $S_1$  has to be larger than the lower experimental bound of  $64.5 \text{ GeV}$  [30]. The upper bound for  $m_{S_1}$  is  $155 \text{ GeV}$ . For  $|\tan\beta|$  there is a lower bound of about 1.4. In the upper right picture the dark

matter condition is imposed improving the upper bound for  $m_{S_1}$  to about  $145 \text{ GeV}$ . The lower left picture shows the mass of the lightest scalar Higgs  $S_1$  in the NMSSM, which is lower than  $150 \text{ GeV}$ . Before applying the UFB-3 constraint (Eq.(27)) there exist scalar Higgses  $S_1$  in the NMSSM lighter than the MSSM Higgs bound of  $64.5 \text{ GeV}$  [30], which are predominantly a Higgs singlet  $N$  [8, 11, 12]. These very light scalar Higgses are now excluded by the UFB-3 constraint (Eq.(27)), which excludes the parameter region with small  $m_0$  and large  $|m_{1/2}|$ . But this parameter region is needed in order to have very light scalar Higgses with a large Higgs singlet portion [13]. In contrast to the MSSM, the lower bound for  $|\tan\beta|$  in the NMSSM is about 2.4. The higher lower bound for  $|\tan\beta|$  follows from the extra third minimum condition (Eq.(11)) in the NMSSM. For larger values of  $|\tan\beta|$  the density of NMSSM solutions decreases, if the UFB-3 constraint (Eq.(27)) is applied. This follows from the fact that the NMSSM solutions with larger  $|\tan\beta|$  are lying in the parameter region with small  $m_0$  and large  $|m_{1/2}|$  [9, 10]. The lower right picture shows only solutions, which fulfill the dark matter condition. In the NMSSM the cosmologically allowed scalar Higgs  $S_1$  is heavier than  $69 \text{ GeV}$  and lighter than  $130 \text{ GeV}$ . In contrast to the MSSM the dark matter condition together with the UFB-3 constraint (Eq.(27)) leads to an upper bound of about 9 for  $|\tan\beta|$  in the NMSSM. However our investigations are restricted to  $|\tan\beta|$  values below 20 as mentioned in section 3.

In the upper left picture of Fig.9 we show the mass of the lighter scalar Higgs  $S_1$  versus the mass of the pseudoscalar Higgs  $P_1$  for the MSSM. In the MSSM  $m_{P_1}$  is larger than  $150 \text{ GeV}$  within our restricted range of  $|\tan\beta|$  values below 20 as mentioned in section 3. The upper right picture shows the cosmologically allowed Higgses. The dark matter condition restricts the mass of the pseudoscalar Higgs  $P_1$  to the range  $200 \text{ GeV} < m_{P_1} \lesssim 2300 \text{ GeV}$ . The lower left picture shows the mass of the lightest scalar Higgs  $S_1$  versus the mass of the lighter pseudoscalar Higgs  $P_1$  for the NMSSM. If the UFB-3 constraint (Eq.(27)) is not applied there exist very light scalar Higgses  $S_1$  correlated with very light pseudoscalar Higgses  $P_1$  which have both a large Higgs singlet portion [8]. With the UFB-3 constraint (Eq.(27)) these very light Higgses are now excluded as already discussed for the very light scalar Higgs  $S_1$  (see Fig.8). For this reason we have now a lower bound of  $200 \text{ GeV}$  for the pseudoscalar Higgs  $P_1$  in the NMSSM for  $|\tan\beta|$  values below 20. In the lower right

picture the dark matter condition is imposed leading to a lower bound of  $250\text{ GeV}$  and an upper bound of  $900\text{ GeV}$  for the lighter pseudoscalar Higgs  $P_1$ . Compared with the MSSM the upper bound for the lighter pseudoscalar Higgs  $P_1$  is somewhat lower in the NMSSM. This follows from the extra third minimum condition (Eq.(11)) in the NMSSM and the suppression of the domain  $m_0 \gg |m_{1/2}|$  in the NMSSM.

## 7 Conclusions

In the present paper we have made a comparison between the MSSM and NMSSM concerning the parameter space and the particle spectra. In contrast to the MSSM, the case  $m_0 \gg |m_{1/2}|$  is disfavored in the NMSSM as discussed in [9] and the squark masses are nearly proportional to the gluino mass (cf. Figs.(6) and (7)). Furthermore the gluino and the lighter u-squark in the NMSSM are heavier than in the MSSM. In the NMSSM the lower bound for the gluino is  $330\text{ GeV}$  and  $370\text{ GeV}$  for the lighter u-squark, whereas the lower bound for the gluino and lighter u-squark in the MSSM is  $250\text{ GeV}$ . In the NMSSM a light stop is excluded by the stronger constraints for the trilinear couplings  $A_{u_i}$ ,  $A_{d_i}$  and  $A_{e_i}$  (Eqs.(17)-(19)) and the UFB-3 constraint (Eq.(27)). This leads to a larger stop mass  $m_{\tilde{t}_1} > 240\text{ GeV}$  in the NMSSM even before considering dark matter constraints. This is in contrast to the MSSM where stops as light as the experimental lower bound of  $63\text{ GeV}$  [25] are allowed. One important difference between the NMSSM and the MSSM is the occurrence of LSP singlinos and light scalar and pseudoscalar Higgs singlets in the NMSSM. Applying the UFB-3 constraint (Eq.(27)) these singlet states are excluded as shown in Fig.4 and Fig.9 and discussed in section 6. In this way the UFB-3 constraint strongly reduces the differences between the NMSSM and the MSSM.

Furthermore we have investigated the consequences of the dark matter condition for the MSSM and NMSSM. Together with the UFB-3 constraint (Eq.(27)) the dark matter condition gives an upper bound of about 9 for  $|\tan\beta|$  in the NMSSM (see Fig.8), whereas in the MSSM larger values of  $|\tan\beta|$  are furthermore allowed within our investigated range of  $|\tan\beta|$  values below 20. For the LSP neutralinos, lightest charginos, gluinos and scalar Higgses  $S_1$  the cosmologically allowed mass ranges are comparable for the MSSM

( $40\text{ GeV} < m_{\tilde{\chi}_1^0} < 240\text{ GeV}$ ,  $85.4\text{ GeV} < m_{\tilde{\chi}_1^+} < 450\text{ GeV}$ ,  $250\text{ GeV} < m_{\tilde{g}} < 1600\text{ GeV}$ ,  $64.5\text{ GeV} < m_{S_1} < 145\text{ GeV}$ ) and for the NMSSM ( $50\text{ GeV} < m_{\tilde{\chi}_1^0} < 260\text{ GeV}$ ,  $90\text{ GeV} < m_{\tilde{\chi}_1^+} < 500\text{ GeV}$ ,  $370\text{ GeV} < m_{\tilde{g}} < 1800\text{ GeV}$ ,  $69\text{ GeV} < m_{S_1} < 130\text{ GeV}$ ). The enhanced lower bound of  $50\text{ GeV}$  and the larger Higgsino portion of the lightest cosmologically allowed LSP neutralinos leads to improved lower bounds for the charginos and gluinos in the NMSSM. Furthermore the dark matter condition slightly improves the lower bounds for the lighter u-squark and lighter stop in the NMSSM to  $390\text{ GeV}$  and  $270\text{ GeV}$ , respectively. In the MSSM, due to Z-pole and Higgs-pole enhanced neutralino pair annihilation, large masses of the selectrons, u-squarks and stops are cosmologically allowed. In contrast, the NMSSM does not allow for large slepton and squark masses at moderate gluino masses (cf. Figs.(5-7)) and the dark matter condition leads to the upper bounds  $m_{\tilde{e}_R} < 450\text{ GeV}$ ,  $m_{\tilde{u}_R} < 1600\text{ GeV}$  and  $m_{\tilde{t}_1} < 1300\text{ GeV}$  at large gluino masses, which are comparable with the MSSM. In comparison with the MSSM the upper bound for the cosmologically allowed pseudoscalar Higgs  $P_1$  is somewhat lower in the NMSSM  $m_{P_1} < 900\text{ GeV}$  (Fig.9).

Despite of the discussed differences, it may be difficult to distinguish experimentally between the MSSM and NMSSM. One possibility is the measurement of smaller couplings of the neutral Higgses in the NMSSM, which result from the mixing of the ordinary Higgs states with the Higgs singlets as discussed in [8, 9] and [11] - [13]. Another possibility suggested in [9, 10] is the search for an additional cascade in the NMSSM, which is produced in the decay of the bino-like second lightest neutralino into the LSP singlino. Since the LSP singlinos are excluded by the UFB-3 constraint this additional cascade is not a way to discriminate between the NMSSM and MSSM any more.

## Acknowledgements

I am grateful to M. Glück and E. Reya for suggestions and many helpful discussions. Also I would like to thank U. Ellwanger and C.A. Savoy for useful conversations. The work has been supported by the 'Graduiertenkolleg am Institut für Physik der Universität Dortmund'.

## Appendix A1: Annihilation cross section

To calculate the relic neutralino density (Eq.(30)) in the NMSSM we need the annihilation cross section of the neutralinos into the different decay products  $X$  and  $Y$ .

$$\tilde{\chi}_1^0(h) \tilde{\chi}_1^0(\bar{h}) \rightarrow X(\lambda_X) Y(\lambda_Y)$$

$\lambda_f = \lambda_X - \lambda_Y$ , where  $\lambda_X$  and  $\lambda_Y$  are the helicities of particle  $X$  and  $Y$ . Within the partial wave formalism the annihilation cross section is obtained [34] as:

$$\sigma_{ann}(\tilde{\chi}_1^0 \tilde{\chi}_1^0 \rightarrow X Y)v = \frac{1}{4} \frac{\bar{\beta}_f}{8\pi s S} \left[ |A(^1S_0)|^2 + \frac{1}{3}(|A(^3P_0)|^2 + |A(^3P_1)|^2 + |A(^3P_2)|^2) \right] \quad (34)$$

$$\bar{\beta}_f = \sqrt{1 - \frac{2(m_X^2 + m_Y^2)}{s} + \frac{(m_X^2 - m_Y^2)^2}{s^2}} \quad (35)$$

$s \approx 4m_{\tilde{\chi}}^2$  is the center of mass energy squared.  $S$  is a symmetry factor, which is 2 if  $X = Y$ . Summation over final helicities is implicit in Eq.(34). The partial wave amplitude  $A(^{2S+1}L_J)$  describes annihilation from an initial state with spin  $S$ , orbital angular momentum  $L$  and total angular momentum  $J$ . The partial wave amplitudes  $A(^{2S+1}L_J)$  for the NMSSM are obtained by slightly modifying the partial wave amplitudes of the MSSM in [34] and by using the corresponding NMSSM couplings. Thereby we have corrected some misprints [44] in [34]. One modification of the neutralino annihilation is the exchange of 5 neutralinos in the NMSSM instead of 4 neutralinos in the MSSM. Other modifications concern the exchange of the scalar Higgses  $S_1$ ,  $S_2$  and  $S_3$  in the NMSSM instead of  $H_1$  and  $H_2$  in the MSSM and the exchange of the pseudoscalar Higgses  $P_1$  and  $P_2$  in the NMSSM instead of  $P$  in the MSSM. In addition the NMSSM coupling  $g_{\alpha-+}$  (Eq.(98)) has to be inserted in Eq.(86). In the MSSM there is only one pseudoscalar Higgs  $P$  and the coupling  $g_{\alpha-+}$  turns out to be 1. In the following the partial wave amplitudes  $A(^{2S+1}L_J)$  of the NMSSM for all decay channels are given in leading order in the relative velocity  $v$  of the non-relativistic neutralinos. Previously we give some NMSSM couplings and definitions. The couplings of the W boson to the chargino  $\tilde{\chi}_j^+$  and the LSP neutralino, which is denoted with index 0 in [34] instead of 1, have the same form in the MSSM and NMSSM, but a different matrix  $N$  (Eq.(15)) enters:

$$O_{0j}^L = -\frac{1}{\sqrt{2}} N_{04} V_{j2} + N_{02} V_{j1} \quad (36)$$

$$O_{0j}^R = \frac{1}{\sqrt{2}} N_{03} U_{j2} + N_{02} U_{j1}. \quad (37)$$

The mass matrix of the charginos is diagonalized by the orthogonal matrices  $U$  and  $V$ , which are explicitly given in [40]. In the NMSSM the couplings of the charged Higgs to the chargino  $\tilde{\chi}_j^+$  and the LSP neutralino has to be modified compared to the MSSM:

$$Q_{0j}^L = N_{04} V_{j1} + \frac{1}{\sqrt{2}} (N_{02} + N_{01} \tan \theta_W) V_{j2} - \frac{\lambda \tan \beta}{g_2} N_{05} V_{j2} \quad (38)$$

$$Q_{0j}^R = N_{03} U_{j1} - \frac{1}{\sqrt{2}} (N_{02} + N_{01} \tan \theta_W) U_{j2} - \frac{\lambda}{g_2 \tan \beta} N_{05} U_{j2}. \quad (39)$$

In the MSSM and NMSSM the coupling of the Z boson to the neutralinos  $\tilde{\chi}_i^0$  and  $\tilde{\chi}_j^0$  is given by:

$$O_{ij}^{\prime L} = -\frac{1}{2} N_{i3} N_{j3} + \frac{1}{2} N_{i4} N_{j4}. \quad (40)$$

In the NMSSM the coupling of the scalar Higgs  $S_a$  to the neutralinos  $\tilde{\chi}_i^0$  and  $\tilde{\chi}_j^0$  changes compared to the MSSM and can be written as:

$$T_{S_a ij} = -U_{a1}^S Q_{ij}'' + U_{a2}^S S_{ij}'' + U_{a3}^S Z_{ij}'' \quad (41)$$

$$Q_{ij}'' = \frac{1}{2 g_2} [N_{i3} (g_2 N_{j2} - g_y N_{j1}) + \sqrt{2} \lambda N_{i4} N_{j5} + (i \leftrightarrow j)] \quad (42)$$

$$S_{ij}'' = \frac{1}{2 g_2} [N_{i4} (g_2 N_{j2} - g_y N_{j1}) - \sqrt{2} \lambda N_{i3} N_{j5} + (i \leftrightarrow j)] \quad (43)$$

$$Z_{ij}'' = \frac{1}{2 g_2} [-\sqrt{2} \lambda N_{i3} N_{j4} + \sqrt{2} k N_{i5} N_{j5} + (i \leftrightarrow j)]. \quad (44)$$

The  $3 \times 3$  mass matrix of the scalar Higgses  $S_i$  [3] in the basis  $(H_{1R}^0, H_{2R}^0, N_R)$  with  $H_{iR}^0 = \sqrt{2} \text{Re}\{H_i^0\}$  ( $i = 1 - 3$ ) is diagonalised by the matrix  $U^S$ . The scalar Higgses  $S_i$  ( $i = 1 - 3$ ) are ordered with increasing mass. The coupling of the pseudoscalar Higgs  $P_\alpha$  to the neutralinos is also different in the MSSM and NMSSM. In the NMSSM this coupling has the following form:

$$T_{P_\alpha ij} = -U_{\alpha 1}^P Q_{ij}''' + U_{\alpha 2}^P S_{ij}''' - U_{\alpha 3}^P Z_{ij}''' \quad (45)$$

$$Q_{ij}''' = \frac{1}{2g_2} [N_{i3} (g_2 N_{j2} - g_y N_{j1}) - \sqrt{2} \lambda N_{i4} N_{j5} + (i \leftrightarrow j)] \quad (46)$$

$$S_{ij}''' = \frac{1}{2g_2} [N_{i4} (g_2 N_{j2} - g_y N_{j1}) + \sqrt{2} \lambda N_{i3} N_{j5} + (i \leftrightarrow j)] \quad (47)$$

$$Z_{ij}''' = Z_{ij}'' \quad (48)$$

The  $3 \times 3$  mass matrix of the pseudoscalar Higgses  $P_\alpha$  and the neutral Goldstone boson [3] in the basis  $(H_{1I}^0, H_{2I}^0, N_I)$  with  $H_{iI}^0 = \sqrt{2} \text{Im}\{H_i^0\}$  ( $i = 1-3$ ) is here diagonalised by the  $3 \times 3$  matrix  $U^P$ . The pseudoscalar Higgses  $P_\alpha$  ( $i = 1, 2$ ) are ordered with increasing mass. In [34] the following definitions are used:

$$\Delta^2 = \frac{m_X^2 + m_Y^2}{2m_{\tilde{\chi}}^2} \quad (49)$$

$$R_X = \frac{m_X}{m_{\tilde{\chi}}}, \text{ etc.} \quad (50)$$

$$P_I = 1 + R_I^2 - (R_X^2 + R_Y^2)/2. \quad (51)$$

$$1. \quad \tilde{\chi}_1^0 \tilde{\chi}_1^0 \rightarrow W^-(\lambda) W^+(\bar{\lambda}).$$

The W bosons are produced by Z boson and scalar Higgs  $S_i$  ( $i = 1, 2, 3$ ) exchange in the s-channel and chargino  $\tilde{\chi}_j^+$  ( $j = 1, 2$ ) exchange in the t- and u-channel.

$$A(^1S_0) : \lambda_f = 0, \lambda = \pm 1$$

$\lambda = 0$

$$\frac{8 v \bar{\beta}_f g_2^2}{\sqrt{3} R_W P_j^2} \left[ \left[ -1 + \Delta^2 + \frac{\delta^2}{2} \right] (K'_j + K''_j) - R_j^+ \left[ 1 + \frac{\delta^2}{2} \right] (K'_j - K''_j) \right] \quad (91)$$

In [34] the following definition is used:

$$\delta^2 = (R_W^2 - R_{H^+}^2)/2. \quad (92)$$

The couplings appearing in the chargino  $\tilde{\chi}_j^+$  exchange are combined to:

$$J'_j = -\frac{1}{4} (O_{0j}^R - O_{0j}^L) (Q_{0j}'^R \sin \beta + Q_{0j}'^L \cos \beta) \quad (93)$$

$$J''_j = -\frac{1}{4} (O_{0j}^R + O_{0j}^L) (Q_{0j}'^R \sin \beta - Q_{0j}'^L \cos \beta) \quad (94)$$

$$K'_j = -\frac{1}{4} (O_{0j}^R - O_{0j}^L) (Q_{0j}'^R \sin \beta - Q_{0j}'^L \cos \beta) \quad (95)$$

$$K''_j = -\frac{1}{4} (O_{0j}^R + O_{0j}^L) (Q_{0j}'^R \sin \beta + Q_{0j}'^L \cos \beta). \quad (96)$$

$L_i$  is the product of the coupling of the scalar Higgs  $S_i$  to the LSP neutralinos and to the  $W$  boson and the charged Higgs. In the NMSSM  $L_i$  is given by:

$$L_i = \frac{1}{2} (U_{i2}^S \cos \beta - U_{i1}^S \sin \beta) T_{S_i 00}. \quad (97)$$

In the NMSSM the coupling  $g_{\alpha-+}$  of the pseudoscalar Higgs  $P_\alpha$  to the  $W$  boson and charged Higgs reads:

$$g_{\alpha-+} = U_{\alpha 2}^P \cos \beta + U_{\alpha 1}^P \sin \beta. \quad (98)$$

In the MSSM with only one pseudoscalar Higgs  $P$  the coupling  $g_{\alpha-+}$  turns out to be 1 [34].

$$6. \quad \tilde{\chi}_1^0 \tilde{\chi}_1^0 \rightarrow S_a S_b \text{ or } P_\alpha P_\beta.$$

The scalar Higgses  $S_a$  and  $S_b$  are produced by scalar Higgs  $S_i$  ( $i = 1, 2, 3$ ) exchange in the s-channel and neutralino  $\tilde{\chi}_j^0$  ( $j = 1 - 5$ ) exchange in the t- and u-channel.

$A(^3P_0)$  :

$$\sqrt{6} v g_2^2 \left[ g_{abi} T_{S_i 00} \frac{R_Z}{4 - R_{S_i}^2 + i G_{S_i}} - 2 T_{S_a 0j} T_{S_b 0j} \frac{1 + R_j}{P_j} + \frac{4}{3} T_{S_a 0j} T_{S_b 0j} \frac{\bar{\beta}_f^2}{P_j^2} \right] \quad (99)$$

$A(^3P_2)$  :

$$- \frac{8}{\sqrt{3}} v \bar{\beta}_f^2 g_2^2 T_{S_a 0j} T_{S_b 0j} \frac{1}{P_j^2} \quad (100)$$

The pseudoscalar Higgses  $P_\alpha$  and  $P_\beta$  are also produced by scalar Higgs  $S_i$  ( $i = 1, 2, 3$ ) exchange and neutralino  $\tilde{\chi}_j^0$  ( $j = 1 - 5$ ) exchange. The corresponding amplitudes for  $P_\alpha$  and  $P_\beta$  production can be obtained by replacing  $a, b$  by  $\alpha, \beta$  or  $S_a, S_b$  by  $P_\alpha, P_\beta$  and  $R_j$  by  $-R_j$ . In the NMSSM the trilinear scalar Higgs coupling  $g_{aaa}$  is given by:

$$\begin{aligned} g_{aaa} = & -\frac{6}{g_2 m_Z} \left( \frac{g_y^2 + g_2^2}{8} \sqrt{2} (v_1 U_{a1}^{S3} + v_2 U_{a2}^{S3} - v_1 U_{a1}^S U_{a2}^{S2} - v_2 U_{a2}^S U_{a1}^{S2}) \right. \\ & + \frac{\lambda^2}{\sqrt{2}} v_2 U_{a2}^S U_{a3}^{S2} + \frac{\lambda^2}{\sqrt{2}} x U_{a3}^S U_{a2}^{S2} + \frac{\lambda^2}{\sqrt{2}} v_1 U_{a1}^S U_{a3}^{S2} + \frac{\lambda^2}{\sqrt{2}} x U_{a3}^S U_{a1}^{S2} \\ & + \frac{\lambda^2}{\sqrt{2}} v_1 U_{a1}^S U_{a2}^{S2} + \frac{\lambda^2}{\sqrt{2}} v_2 U_{a2}^S U_{a1}^{S2} + \sqrt{2} k^2 x U_{a3}^{S3} \\ & - \frac{\lambda k}{\sqrt{2}} v_1 U_{a2}^S U_{a3}^{S2} - \frac{\lambda k}{\sqrt{2}} v_2 U_{a1}^S U_{a3}^{S2} - \sqrt{2} \lambda k x U_{a1}^S U_{a2}^S U_{a3}^S \\ & \left. - \frac{\lambda A_\lambda}{\sqrt{2}} U_{a1}^S U_{a2}^S U_{a3}^S - \frac{k A_k}{3 \sqrt{2}} U_{a3}^{S3} \right). \quad (101) \end{aligned}$$

The trilinear scalar Higgs coupling  $g_{aab}$  (or  $g_{aba}$ ) has the following form:

$$\begin{aligned} g_{aab} = g_{aba} = & -\frac{2}{g_2 m_Z} \left( \frac{g_y^2 + g_2^2}{8} \sqrt{2} (3 v_1 U_{b1}^S U_{a1}^{S2} + 3 v_2 U_{b2}^S U_{a2}^{S2} - v_1 U_{b1}^S U_{a2}^{S2} \right. \\ & \left. - 2 v_1 U_{a1}^S U_{b2}^S U_{a2}^S - v_2 U_{b2}^S U_{a1}^{S2} - 2 v_2 U_{a2}^S U_{b1}^S U_{a1}^S) \right) \end{aligned}$$

$$\begin{aligned}
& + \frac{\lambda^2 v_2 - \lambda k v_1}{\sqrt{2}} (U_{b2}^S U_{a3}^{S2} + 2 U_{a2}^S U_{b3}^S U_{a3}^S) + \frac{\lambda^2 x}{\sqrt{2}} (U_{b3}^S U_{a2}^{S2} + 2 U_{a3}^S U_{b2}^S U_{a2}^S) \\
& + \frac{\lambda^2 v_1 - \lambda k v_2}{\sqrt{2}} (U_{b1}^S U_{a3}^{S2} + 2 U_{a1}^S U_{b3}^S U_{a3}^S) + \frac{\lambda^2 x}{\sqrt{2}} (U_{b3}^S U_{a1}^{S2} + 2 U_{a3}^S U_{b1}^S U_{a1}^S) \\
& + \frac{\lambda^2 v_1}{\sqrt{2}} (U_{b1}^S U_{a2}^{S2} + 2 U_{a1}^S U_{b2}^S U_{a2}^S) + \frac{\lambda^2 v_2}{\sqrt{2}} (U_{b2}^S U_{a1}^{S2} + 2 U_{a2}^S U_{b1}^S U_{a1}^S) \\

$\lambda_f = \pm 1$

$$\begin{aligned} & \sqrt{2} v \left[ \lambda_f \bar{\beta}_f (X'^2_{a0} + W'^2_{a0}) \left[ -\frac{1}{P_1} + \frac{1}{P_1^2} \right] + (X'^2_{a0} - W'^2_{a0}) \left[ \frac{1}{P_1} - \frac{\bar{\beta}_f^2}{P_1^2} \right] \right. \\ & \quad \left. + 2 \bar{\beta}_f \lambda_f X'_{a0} W'_{a0} \frac{R_f}{P_1^2} \right] + (X'_{a0} \leftrightarrow Z'_{a0}, W'_{a0} \leftrightarrow Y'_{a0}, P_1 \leftrightarrow P_2) \\ & + 2 \sqrt{2} v \frac{g_2^2}{\cos^2 \theta_W} O''^L_{00} [\lambda_f T_{3a} \bar{\beta}_f - (T_{3a} - 2 e_{f_a} \sin^2 \theta_W)] \frac{1}{4 - R_Z^2 + i G_Z} \end{aligned} \quad (116)$$

$A(^3P_2) : \lambda_f = 0$

$$\begin{aligned} & -\frac{2}{\sqrt{3}} v \bar{\beta}_f \frac{1}{P_1^2} \left[ R_f (X'^2_{a0} + W'^2_{a0}) + 2 X'_{a0} W'_{a0} \right] \\ & + (X'_{a0} \leftrightarrow Z'_{a0}, W'_{a0} \leftrightarrow Y'_{a0}, P_1 \leftrightarrow P_2) \end{aligned} \quad (117)$$

$\lambda_f = \pm 1$

$$\begin{aligned} & \sqrt{2} v \bar{\beta}_f \frac{1}{P_1^2} [-(X'^2_{a0} + W'^2_{a0}) + \bar{\beta}_f \lambda_f (X'^2_{a0} - W'^2_{a0}) - 2 R_f X'_{a0} W'_{a0}] \\ & + (X'_{a0} \leftrightarrow Z'_{a0}, W'_{a0} \leftrightarrow Y'_{a0}, P_1 \leftrightarrow P_2). \end{aligned} \quad (118)$$

The sfermion mass eigenstates  $\tilde{f}_{1,2}$  are defined by

$$\tilde{f}_1 = \tilde{f}_L \cos \theta_f + \tilde{f}_R \sin \theta_f \quad (119)$$

$$\tilde{f}_2 = -\tilde{f}_L \sin \theta_f + \tilde{f}_R \cos \theta_f. \quad (120)$$

The couplings of the mixed sfermion  $\tilde{f}_{1,2}$  to the fermion and LSP neutralino can be written as:

$$X'_{a0} = X_{a0} \cos \theta_f + Z_{a0} \sin \theta_f \quad (121)$$

$$W'_{a0} = Z_{a0} \cos \theta_f + Y_{a0} \sin \theta_f \quad (122)$$

$$Z'_{a0} = -X_{a0} \sin \theta_f + Z_{a0} \cos \theta_f \quad (123)$$

$$Y'_{a0} = -Z_{a0} \sin \theta_f + Y_{a0} \cos \theta_f, \quad (124)$$

where the couplings of the unmixed sfermion  $\tilde{f}_{L,R}$  to the fermion and LSP neutralino are given by:

$$X_{a0} = -\sqrt{2} g_2 [T_{3a} N_{02} - \tan \theta_W (T_{3a} - e_{f_a}) N_{01}] \quad (125)$$

$$Y_{a0} = \sqrt{2} g_2 \tan \theta_W e_{f_a} N_{01} \quad (126)$$

$$Z_{u0} = -\frac{g_2 m_u}{\sqrt{2} \sin \beta m_W} N_{04} \quad (127)$$

$$Z_{d0} = -\frac{g_2 m_d}{\sqrt{2} \cos \beta m_W} N_{03}. \quad (128)$$

In the NMSSM the couplings of the Higgses to the fermions have to be modified compared to the MSSM:

$$h_{S_i u} = -\frac{g_2 m_u U_{i2}^S}{2 \sin \beta m_W} \quad h_{S_i d} = -\frac{g_2 m_d U_{i1}^S}{2 \cos \beta m_W} \quad (129)$$

$$h_{P_{\alpha} u} = -\frac{g_2 m_u U_{\alpha 2}^P}{2 \sin \beta m_W} \quad h_{P_{\alpha} d} = -\frac{g_2 m_d U_{\alpha 1}^P}{2 \cos \beta m_W}. \quad (130)$$

## Appendix A2: Renormalisation Group Equations

For completeness we also give here the 1 loop SUSY RGEs [18] for the parameters in the NMSSM with our conventions.  $Q$  is the running mass scale in the variable  $t = \log(Q/M_{weak})$ .

$$\frac{d}{dt} g_y = \frac{11}{16 \pi^2} g_y^3 \quad (131)$$

$$\frac{d}{dt} g_2 = \frac{1}{16 \pi^2} g_2^3 \quad (132)$$

$$\frac{d}{dt} g_3 = -\frac{3}{16 \pi^2} g_3^3 \quad (133)$$

$$\frac{d}{dt} \lambda = \frac{1}{8 \pi^2} \left( k^2 + 2 \lambda^2 + \frac{3}{2} h_t^2 - \frac{3}{2} g_2^2 - \frac{1}{2} g_y^2 \right) \lambda \quad (134)$$

$$\frac{d}{dt} k = \frac{3}{8 \pi^2} (k^2 + \lambda^2) k \quad (135)$$

$$\frac{d}{dt} h_t = \frac{1}{8 \pi^2} \left( \frac{1}{2} \lambda^2 + 3 h_t^2 - \frac{8}{3} g_3^2 - \frac{3}{2} g_2^2 - \frac{13}{18} g_y^2 \right) h_t \quad (136)$$

$$\begin{aligned} \frac{d}{dt} A_\lambda = \frac{1}{8 \pi^2} (4 \lambda^2 A_\lambda - 2 k^2 A_k - 3 h_t^2 A_{U_3} \\ - 3 g_2^2 M_2 - g_y^2 M_1) \end{aligned} \quad (137)$$

$$\frac{d}{dt} A_k = \frac{6}{8 \pi^2} (-\lambda^2 A_\lambda + k^2 A_k) \quad (138)$$

$$\begin{aligned} \frac{d}{dt} A_{U_i} = \frac{1}{8 \pi^2} \left( -\lambda^2 A_\lambda + 3 (1 + \delta_{i3}) h_t^2 A_{U_3} \right. \\ \left. + \frac{16}{3} g_3^2 M_3 + 3 g_2^2 M_2 + \frac{13}{9} g_y^2 M_1 \right) \end{aligned} \quad (139)$$

$$\begin{aligned} \frac{d}{dt} A_{D_i} = \frac{1}{8 \pi^2} \left( -\lambda^2 A_\lambda + \delta_{i3} h_t^2 A_{U_3} \right. \\ \left. + \frac{16}{3} g_3^2 M_3 + 3 g_2^2 M_2 + \frac{7}{9} g_y^2 M_1 \right) \end{aligned} \quad (140)$$

$$\frac{d}{dt} A_{E_i} = \frac{1}{8 \pi^2} (-\lambda^2 A_\lambda + 3 g_2^2 M_2 + 3 g_y^2 M_1) \quad (141)$$

$$\begin{aligned} \frac{d}{dt} m_N^2 = \frac{1}{8 \pi^2} [2 \lambda^2 (m_N^2 + m_{H_1}^2 + m_{H_2}^2 + A_\lambda^2) \\ + 2 k^2 (3 m_N^2 + A_k^2)] \end{aligned} \quad (142)$$

$$\begin{aligned} \frac{d}{dt} m_{H_1}^2 = \frac{1}{8 \pi^2} [\lambda^2 (m_N^2 + m_{H_1}^2 + m_{H_2}^2 + A_\lambda^2) \\ - 3 g_2^2 M_2^2 - g_y^2 M_1^2] \end{aligned} \quad (143)$$

$$\frac{d}{dt} m_{H_2}^2 = \frac{d}{dt} m_{H_1}^2 + \frac{3}{8 \pi^2} h_t^2 (m_{H_2}^2 + m_{U_3}^2 + m_{Q_3}^2 + A_{U_3}^2) \quad (144)$$

$$\begin{aligned} \frac{d}{dt} m_{Q_i}^2 &= \frac{1}{8\pi^2} \left[ \delta_{i3} h_t^2 (m_{H_2}^2 + m_{U_3}^2 + m_{Q_3}^2 + A_{U_3}^2) \right. \\ &\quad \left. - \frac{16}{3} g_3^2 M_3^2 - 3 g_2^2 M_2^2 - \frac{1}{9} g_y^2 M_1^2 \right] \end{aligned} \quad (145)$$

$$\begin{aligned} \frac{d}{dt} m_{U_i}^2 &= \frac{1}{8\pi^2} \left[ 2 \delta_{i3} h_t^2 (m_{H_2}^2 + m_{U_3}^2 + m_{Q_3}^2 + A_{U_3}^2) \right. \\ &\quad \left. - \frac{16}{3} g_3^2 M_3^2 - \frac{16}{9} g_y^2 M_1^2 \right] \end{aligned} \quad (146)$$

$$\frac{d}{dt} m_{D_i}^2 = \frac{1}{8\pi^2} \left( -\frac{16}{3} g_3^2 M_3^2 - \frac{4}{9} g_y^2 M_1^2 \right) \quad (147)$$

$$\frac{d}{dt} m_{L_i}^2 = \frac{1}{8\pi^2} (-3 g_2^2 M_2^2 - g_y^2 M_1^2) \quad (148)$$

$$\frac{d}{dt} m_{E_i}^2 = \frac{1}{8\pi^2} (-4 g_y^2 M_1^2) \quad (149)$$

$$\frac{d}{dt} M_1 = \frac{11}{8\pi^2} g_y^2 M_1 \quad (150)$$

$$\frac{d}{dt} M_2 = \frac{1}{8\pi^2} g_2^2 M_2 \quad (151)$$

$$\frac{d}{dt} M_3 = -\frac{3}{8\pi^2} g_3^2 M_3 \quad (152)$$

## Figure Captions

**Fig 1** The scalar mass  $m_0$  versus the gaugino mass  $|m_{1/2}|$ . The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 2** The trilinear coupling  $|A_0|$  versus the scalar mass  $m_0$ . The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 3** The gaugino mass  $|M_2|$  versus the Higgs mixing parameter  $\mu$  both taken at the electroweak scale. The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 4** The bino portion of the LSP neutralino versus the mass of the LSP neutralino. The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 5** The mass of the lighter chargino versus the lighter selectron mass. The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 6** The mass of the lighter u-squark versus the gluino mass. The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 7** The mass of the lighter stop versus the gluino mass. The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 8** The mass of the lightest scalar Higgs  $S_1$  versus  $|\tan\beta|$ . The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.

**Fig 9** The mass of the lightest scalar Higgs  $S_1$  versus the mass of the lightest pseudoscalar Higgs  $P_1$ . The upper pictures are for the MSSM, the lower pictures are for the NMSSM. In the right pictures the dark matter condition is imposed.
